FOREWORD

The National Statistics Bureau (NSB), with the support of United Nations Population Fund (UNFPA), Bhutan brought out a National Level Population Projections in 2007. A Component method was adopted in determining the future population size. The report provides population data projected at national level till 2030 with the base line data of the Population and Housing Census of Bhutan (PHCB) 2005.

The current publication presents projections at Dzongkhag level disaggregated by age group, sex and areas upto 2015. The exponential growth model together with ratio type methods are adopted for this sub-national projection. The age-sex distribution is estimated as the ratio of the population in each age group of national population. The adjustment of the data as per new administrative boundaries of the Dzongkhags was necessitated to ensure the comparability of population data over time.

Projected population disaggregated by age, sex, urban and rural areas is necessary towards fulfilling specific goals and objectives. Moreover, the data on future course of population change backed by knowledge about the potential impact and effects of such interventions is useful to reinforce the development activities.

The accuracy of any projection is conditional on the reliability of the base population estimates, the component data, and the degree to which the underlying assumptions correspond to future trends. Projections are not predictions; they are instead an effort to create plausible scenarios based on assumptions regarding the components of population growth, which are themselves subject to uncertainty. Accordingly, it cannot be claimed that the values observed in the coming years will always remain within the range implied by the projection exercises.

The NSB would like to acknowledge the support of UN System and UNICEF in particular for its technical support and in bringing out this report. We hope that the report provides the policy makers, planners, development partners, and other stakeholders the required information for micro-level planning and program implementation.

(Kuenga Tshering)
DIRECTOR

EXECUTIVE SUMMARY

Population projection is a means to determine the future course of population change in its size, age-sex composition, its growth and geographic distribution. It provides the future population parameters in sufficient detail for use in socio-economic development planning.

One of the many utilities of population projections, the foremost importance is for adequate planning at the national and Dzongkhag levels. Detailed information about the characteristics of the society and its population is necessary to fulfill specific goals of government programs to improve living conditions. Data on future course of population change along with knowledge about the potential impact and effects of such programs is useful to reinforce development activities for society and its development. Population data are useful as a framework for precise formulation of strategies for a country's development in improving the quality of life of the population.

During the process of projection, data from the Population and Housing Census of Bhutan (PHCB) 2005 was used as a basis. The base data after necessary evaluation was used along with fertility, mortality and migration data sourced from PHCB 2005, National Health Surveys, and other official statistics.

National level projection: *For the national level projection, a Component method is adopted which takes into account the influences of fertility, mortality and migration in determining the future population size.*

The population of Bhutan is projected to increase by 19 percent in 2015 reaching about 757,042 from the base population of 634,982 in 2005. The implied population growth rate is observed at 1.8 percent. From the PHCB 2005, the death rate is estimated at 7.1 and birth rate of 26.1 per thousand populations

The sex ratio at birth in 2005 was 101 males for every 100 females which is indicative of better reliability of data. The general sex ratio was 111 males for every 100 females. High sex ratio in Bhutan is attributable to the age-sex selective expatriates working in Bhutan. Such a scenario is assumed to prevail during the population projection period.

Dzongkhag level projection: *For the Dzongkhag level population projection, exponential growth model together with ratio type methods are adopted. The age-sex distribution in the Dzongkhag population is estimated as the ratio of the population in each age group of national population. The adjustment of data as per the new administrative boundaries of the Dzongkhags is done to ensure the comparability of population data over time.*

The population of Thimphu is projected to reach 116,012 in 2015, an increase of 25 percent from 2005 with an average growth rate of 2.2 percent, which is the highest among the Dzongkhags. Pemagatshel has the least average growth rate of 1.2 percent and its population is projected at 25,180 in 2015 from 22,287 in 2005.

Gasa is expected to have an additional population of about 600 persons by 2015 making its population of 3,692 persons, thus still remaining the least populated Dzongkhag.

Urban-rural projection: *The URGD method is used to project urban and rural population when total national population has been already projected.*

The population in urban areas was 13.07 percent in 1985; 30.9 percent in 2005, based upon which urban and rural population growth rates were estimated separately from the urban population time series data

Urban population is projected to grow from 196,111 persons in 2005 to about 294,042 in 2015. Urban population is estimated to grow at an average annual rate of 4.2 percent while rural population will grow comparatively at a much lower rate of less than 1 percent.

I. INTRODUCTION

A population projection is a means to determine future population change in terms of size, growth pattern, age and sex composition, and geographic distribution. It provides future population parameters in sufficient detail for use in socioeconomic development planning.

Data from the PHCB 2005 were used as a baseline for this projection for 2006-2015, along with previously gathered data on fertility, mortality and migration. The 2005 base population was then projected using a set of assumptions for national level, urban and rural areas, and Dzongkhags. The principal sources of data for projections thus are the PHCB 2005 and previous National Health Surveys, as well as other published sources of official statistics by the National Statistics Bureau, the Ministry of Health and others.

II. USE OF POPULATION DATA

To keep up with development and to make strategic planning, users require not only the current data but the knowledge of the future level, trend and pattern of population change that becomes invaluable tool to formulate plans and programs. The Dzongkhag level projections are useful for micro-level planning and program formulation.

Of the many uses for population projections in Bhutan, most important is for strengthening of adequate planning at the national and Dzongkhag levels. Detailed information about characteristics of the society and its population is necessary to promote formulation of effective strategies and fulfill specific goals of Government programmes, thereby improving living conditions and overall quality of life. At the same time, data on future population changes, along with knowledge about the potential impact of programmes, are invaluable for strategic planning and reinforcement of development activities. In particular, Dzongkhag projections are useful for micro-level planning and programme formulation.

The results of PHCB 2005 supplemented by results of other surveys or publications makes it possible to widen the scope and usefulness of the existing data for practical purposes. Regular collection of population data complemented by vital registration system and other surveys would improve the data availability, reliability, timeliness and scope of data within the country.

III. BASE DATA ON POPULATION

The methodology for projecting the population at national level used age and sex composition of the population resulting from the PHCB 2005, given that current age-sex distribution influences future age-sex distribution through the components of population change, i.e., fertility, mortality and migration. It should be noted that distribution of age-sex data has been desirably smoothed by the widely held view that age returns from census enumerations are not always perfectly reported. Evaluation of the age and sex structure of base population using various methods indicates a slight deviation from the expected pattern, particularly at younger ages and for the working-age population. Various methods to detect age misreporting, including

analysis of digit preference, age ratios and sex ratios has been carried out. The age-sex structure of the population in 2005 then forms the basis for carrying out national, urban-rural and dzongkhag-level projections

Before making projections, it is important to evaluate the available data for reliability. The age-sex data was evaluated for coverage errors, responses errors, and misreporting of ages which are normally inherent in data collected through massive national level field operations, such as the census.

One of the evaluative measures to understand the quality of data is to find out the digit preference in the age specific data.

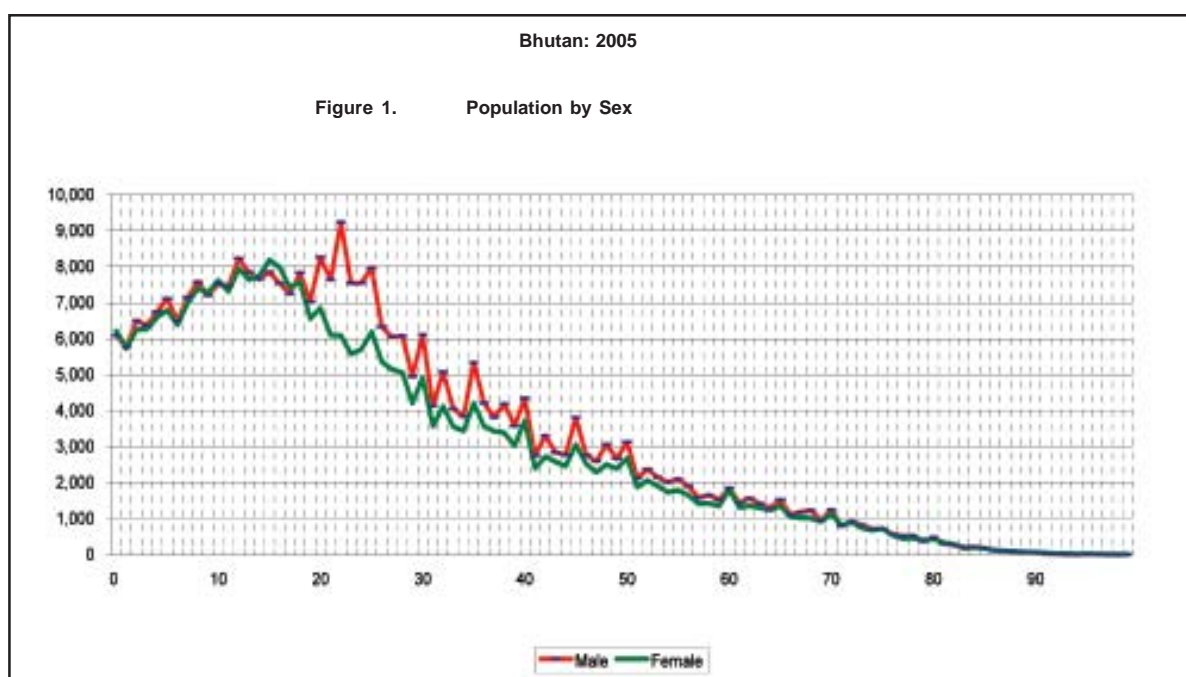

The digit preference index measures the quality of age data collected in the PHCB 2005. Generally, data on age is difficult to come by with desired quality from surveys and census. Respondents may have their reasons to round off their age reporting to the nearest 5 and 0 or has preference to report ages in certain choices or preference for digits. For certain reasons of their own, persons in a certain community might report an age with digits ending with 1, 2 or 3 etc. Whenever respondents tend to report their ages ending with certain digits, it leads to abnormal data distributions, for e.g. comparatively greater number of population might be observed in certain ages as compared to the neighbouring ages. This is called age heaping. When there is age heaping of responses in certain ages, the base population needs to be subjected to age smoothening procedures before population projections.

Digit preference in age reporting was assessed through Myers index, Whipples Index , among others. These indices not only provide an overall idea of the extent of age misreporting but also indicate the preference for certain terminal digits in age reporting.

The value of Whipples Index measures the age-heaping of ages with terminal digits 0 and 5. It is close to 1 when there is no particular concentration of ages ending in 0 and 5; and higher the index, the greater the concentration of ages ending in 0 and 5. Whipples index for Bhutan is estimated at 1.18 for males, 1.15 for females, and 1.16 for both sexes suggesting an acceptable level of age data.

Myers Index, on the other hand, evaluates the preference for ages ending in digits 0 to 9. The range of the index extends from 0, when there is no preference or avoidance of a particular digit, to 9, when all ages are reported in a single terminal digit. For Bhutan, the Myers index is estimated at 7.7 for males, 5.6 for females and 6.5 for both sexes, indicating a satisfactory level of reliability in age data from the PHCB 2005.

Graphical representation of the base age-sex population distribution is presented below.

Overall, the male and female base population by age reveals no significant heaping except for minor irregularities at certain ages

For most census tabulations, sex-age data, when presented in five-year age groups, levels out certain irregularities prominent in single-year age data. For the evaluation of such grouped data, the United Nations Secretariat Method (UN Sex-Age Accuracy Index) is applied to identify distortions and used as a basis for necessary adjustments before making projections.

Sex Ratio: Sex ratio is an analytical tool that can be easily calculated by dividing the male population in a given age (or age group) by the female population in the same age (or age group), times 100. In a normal population, the sex ratio is generally observed to be in the range of 100 to 105. Information on sex ratio can be used to assess the quality of data. Successive differences between one age group and the next are computed to generate sex ratio scores. This, along with the age ratio score, is used to compute the United Nations Joint Score that measures the accuracy of the sex-age returns.

The level of the sex ratio depends on the number of male and female births and on the mortality of the population. All populations have more male than female births, and thus the sex ratio at the early ages is expected to be slightly more than 100. Based on the reported PHCB 2005 data, the sex ratio at birth was 101 males per 100 females, while overall sex ratio was 111 males per 100 females. The higher sex ratio in the general population is mainly because of the sex-age selectivity of expatriate workers. It is assumed that the number of expatriates in Bhutan will remain constant throughout the projection period. Because this section of the population will have a bearing upon all social and economic activities, as well as use of social services, the population projections includes it.

As mentioned, higher sex ratio is observed in the population owing to sex selective expatriate works in the country. This pattern may be observed in the result tables in which male population exceeds females with the peak between ages 20-27 or generally in the working age groups. The highest sex ratio might be observed in Chhukha Dzongkhag where the infrastructural development was prominent during the PHCB 2005.

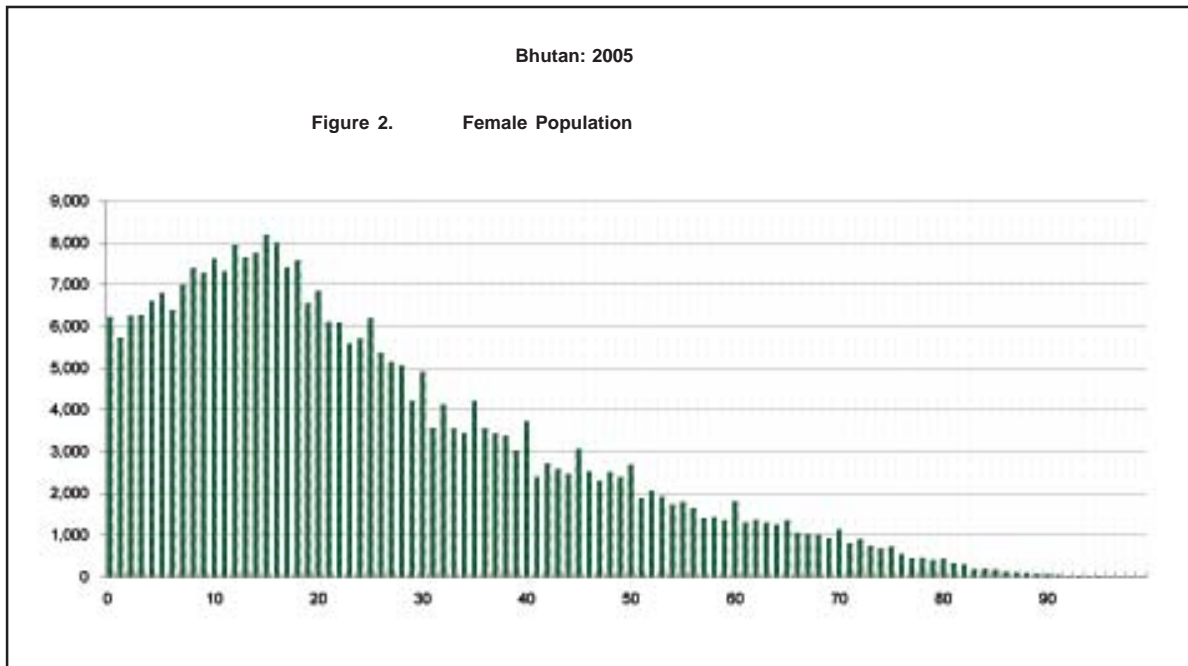

Age ratio score is defined here as the ratio of persons in age groups, as follows:

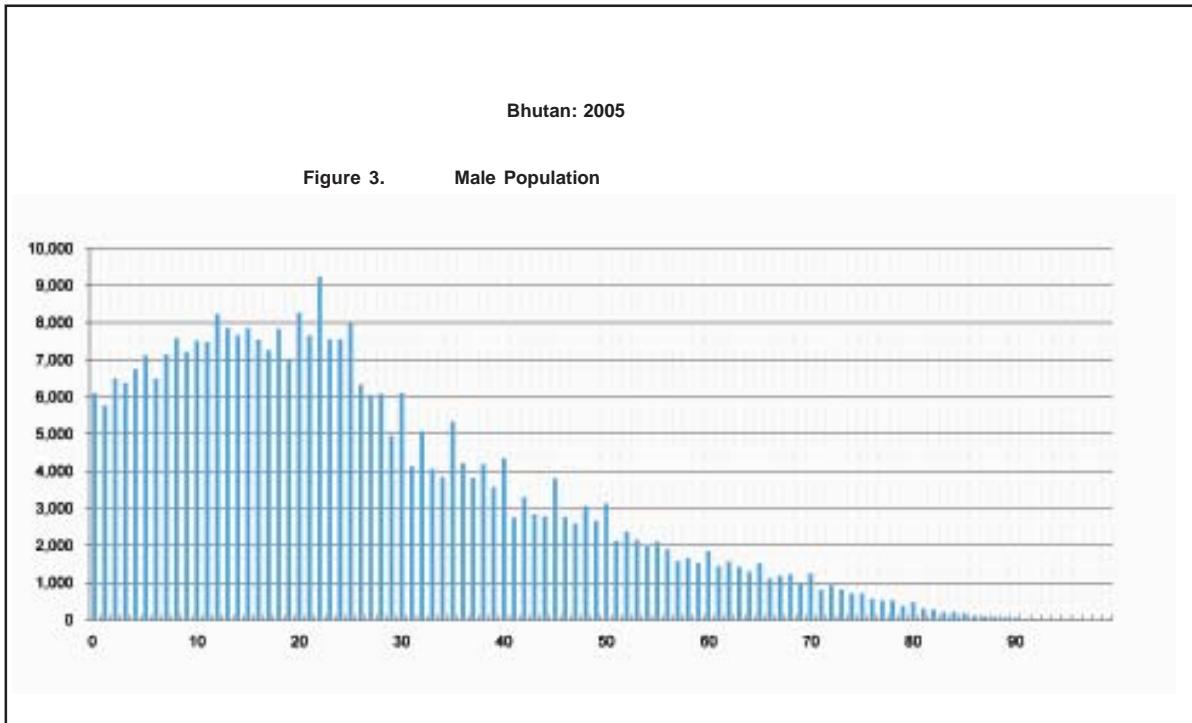

$$\text{Age Ratio} = \{2*(P_x)/P_{x-1} + P_{x+1}\} * 100$$

The larger the abrupt departure of this ratio from values close to 100, the larger the possibility of errors in the data.

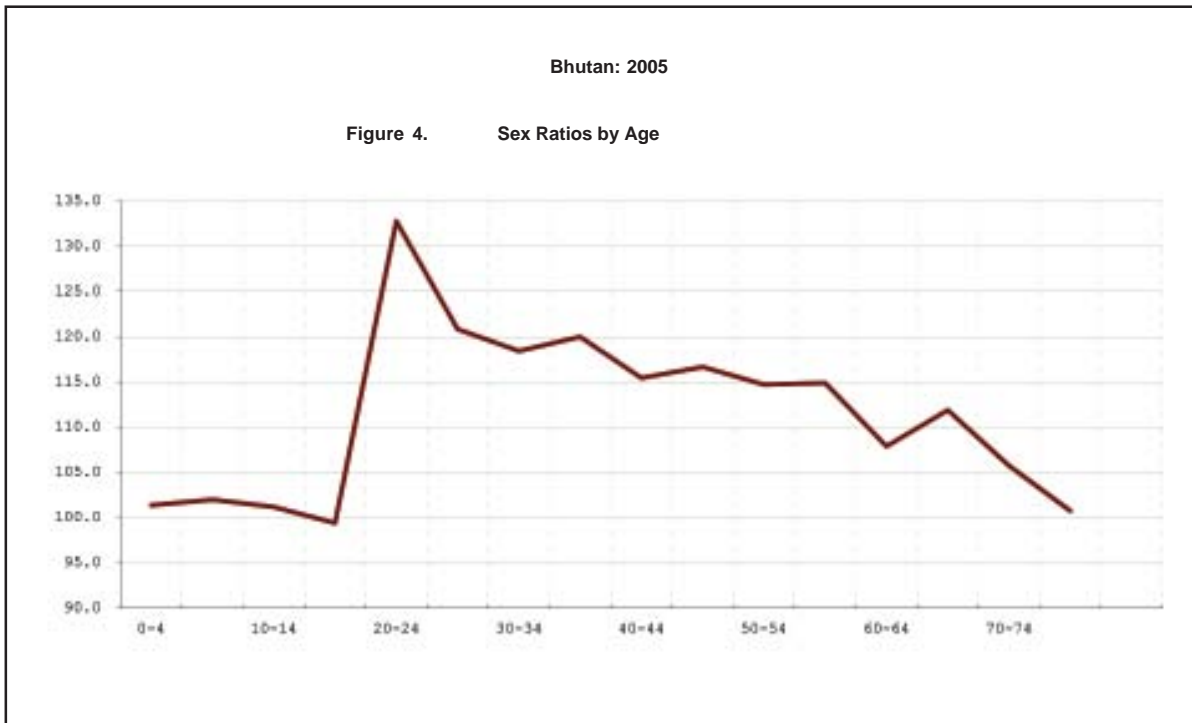

A sex ratio score or age ratio score above may empirically be regarded as in the “high range,” where given sex-age data are suspected as notably affected by errors other than actual fluctuations in population trends. A Joint Score Index <20 indicates accurate; JS 20-40 is inaccurate; and >40 is highly inaccurate. The UN Joint Score for Bhutan 2005 data is 27. Upon close observation of the data, there is a sizeable number of persons between the ages of 18 and 60 who came into the country as expatriate workers. Therefore, the index is compounded by this impact of sex-age selective migrants.

The graphical representation of the data before smoothening is presented below

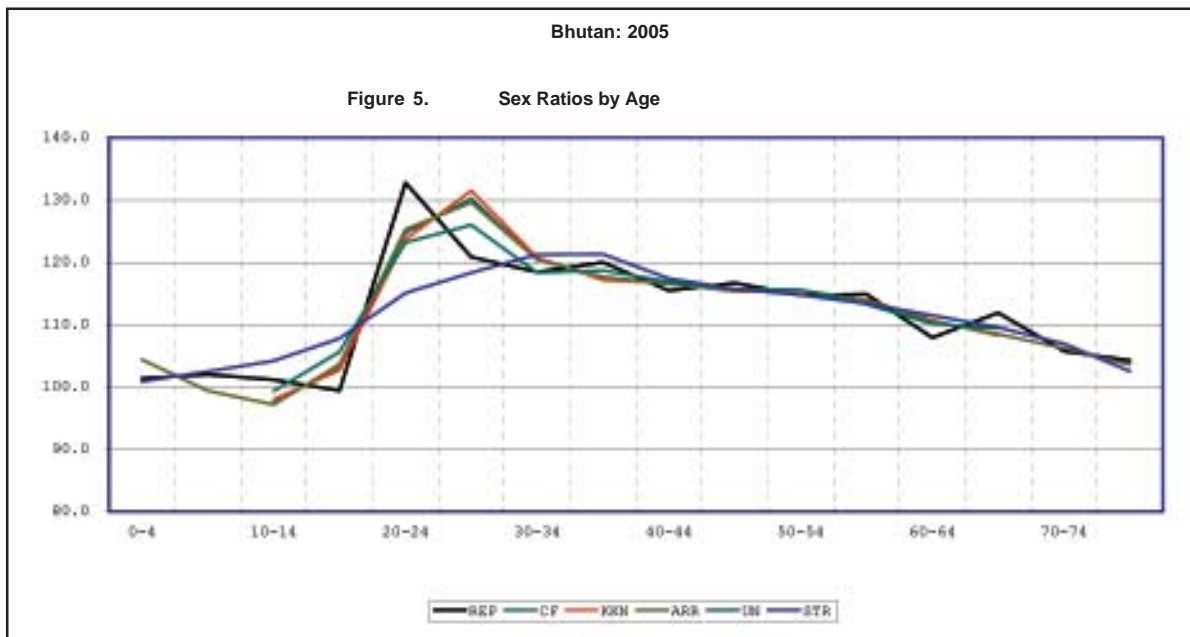

Overall sex ratio for the population of Bhutan in 2005 before smoothing is presented below.

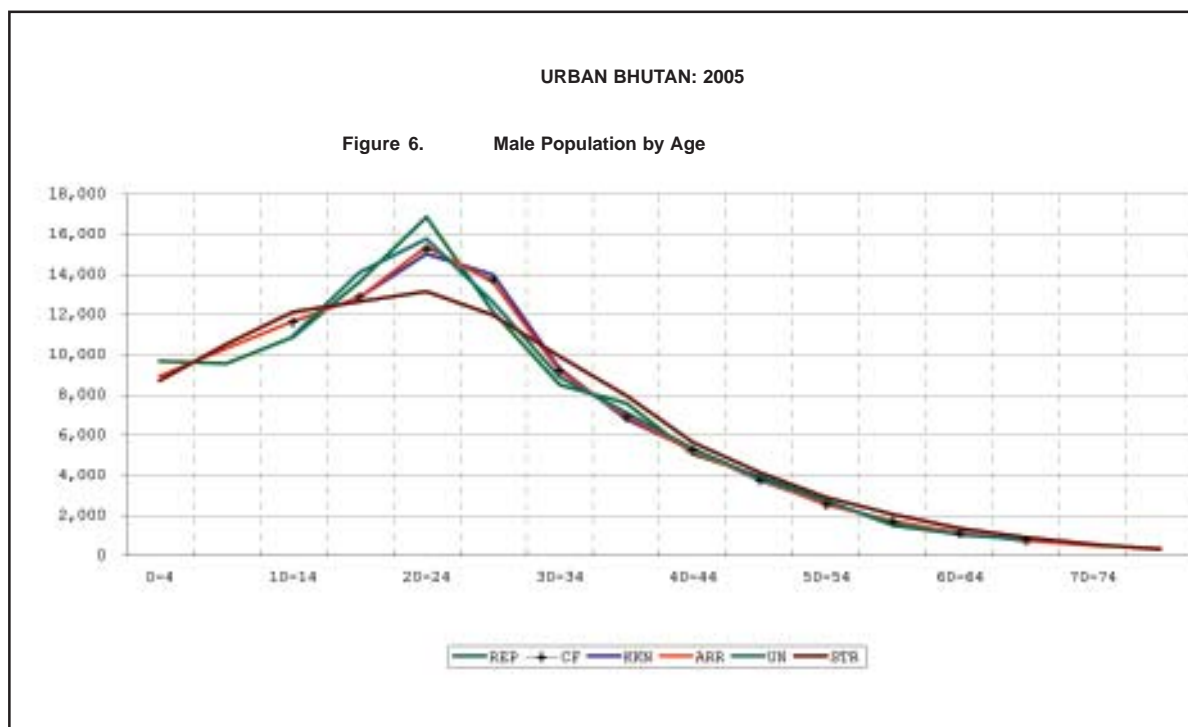

Evaluation of the base population is important as the basis for the subsequent population and its age-sex distribution. Any inconsistencies in the base population, particularly in the younger ages, thus will have significant impact.

Of the many available methods of smoothening, a strong moving average was used to smoothen the base population age-sex data (Figure 5). The graph represents the sex ratios by age group against the reported data and the results of smoothening through various procedures. In the legend, REP means Reported Data; CF means Carrier-Farraq; KKN means Karup-King Newton; ARR means Arriaga; UN means United Nations Method; and STR is the Strong moving average method.

Population projection for urban population is undertaken separately by adopting the Urban Rural Growth Difference Model. Before carrying out population projection, the base population of urban and rural areas was smoothened. The smoothened male population in the urban areas in 2005 is presented in the graph below.

IV. NATIONAL PROJECTION

The component method is used to project the national level population. This method takes into account the influences of fertility, mortality and migration collectively in determining the future population size, under some assumptions relating to future levels, patterns and trends. It is then used to project the population into the future. This method is based upon refined indicators such as the age specific rates of fertility, mortality and migration rates. The process involves the survival estimates from Life Tables which then are used to survive forward the population at the base period into the future period of time. This survival rates are applied to each age group to obtain projected population of the future. For estimations of fertility, mortality and population projections, demographic softwares viz; MortPack, PAS and DemProj were used.

Usually, the live births and deaths in the past one single year are more often under-covered as well as subject to fluctuations from year to year. Fertility estimates based on Child Ever Born takes into account the birth history of women in the reproductive ages and is expected to be more reliable. Therefore, total fertility resulting from the calculation using Child Ever Born by women of reproductive ages is considered as input to the current population projection exercises.

The national population projection in the earlier publication was projected without smoothening the base population. The current projection however, is based on the smoothened age-sex distribution of the base population at the national level and urban-rural levels. The

overall national projected population in the two documents has the same total projected population size except that data distributed across age groups in these two results may vary.

The population of Bhutan is projected to grow from 634,982 persons in 2005 to 757,042 in 2015. The birth rate, measured directly based on the number of live births in the year preceding the census, is 19.7 per 1,000. Similarly, the death rate from the observed number of deaths in the year preceding the census is 7.1 per 1,000. However, the use of age-specific fertility based upon Child Ever Born (P/F Method) and age-specific mortality generate population projections yielding an implied birth rate of 26.1 per 1,000 and a death rate of 7.1 per 1,000, with implied population growth of 1.8 percent per annum at the national level resulting from the population projection.

Direct measures based upon births in past one year before census gave rise to Total Fertility Rate of 2.6. An alternative method based upon children ever born however, results to a TFR of 3.6 for Bhutan at the national level. This figure when compared to past trend of fertility data along with the estimations of life expectancy at birth was used for the national population projection.

V. DZONGKHAG LEVEL POPULATION PROJECTION

Dzongkhag level population is projected using individual Dzongkhag growth rates derived based on births, deaths and inter Dzongkhag migration rates.

Migration from one Dzongkhag to another varies among Dzongkhags according to the level of migration. Certain Dzongkhags are therefore growing comparatively faster than the others during the projection period. Thimphu, Chhukha and Paro Dzongkhags are the highest recipients of migrants while Zhemgang, Pemagatshel, and Lhuentse Dzongkhags are losers of population through migration.

Average annual rate of growth during the projection period 2006-2015 is presented in the following table.

Average annual growth rates of Dzongkhags, 2006-2015			
Dzongkhag	Growth rate	Dzongkhag	Growth rate
Bumthang	1.6	Samdrup	1.8
Chukha	1.7	Samtse	1.6
Dagana	1.9	Sarpang	2.0
Gasa	1.6	Thimphu	2.2
Haa	1.4	Trashigang	1.3
Lhuentse	1.3	Trashiyangtse	1.6
Monggar	1.7	Trongsa	1.7
Paro	1.6	Tsirang	1.5
Pemagatshel	1.2	Wangdue	1.8
Punakha	1.7	Zhemgang	1.4

The in-migration and out-migration is an important component for change in population size at the Dzongkhag levels. The different levels of migrations among the Dzongkhags give rise to varying growth rate for individual Dzongkhag.

In carrying out the Dzongkhag level population projections, it is assumed that the level of migration, number of births and deaths does not change drastically from the level observed in 2005 during the projection period.

VI. DZONGKHAG POPULATION AGE-SEX COMPOSITION PROJECTION

Under the knowledge of projected age-sex distribution of the national population, age-sex distribution of the Dzongkhag population was done using the ratio of proportion of population in each age-sex group of the Dzongkhag to the corresponding proportion at national level. For e.g. the ratio for age 5-9 age group may be given as:

$$R_{5-9}^i = P_{5-9}^i / P_{5-9}^n$$

Where R_i is the age specific ratio of Dzongkhag population to the age specific population at the national level.

In applying the method, it was assumed that the ratio “R” will remain the same during the projection period. It is the ratio of proportion of population at each age in the Dzongkhag to the national would not change within the short projection period

Age-sex distribution for the projected urban and rural areas, and the Dzongkhags were thus derived by applying the ratio method.

The administrative boundaries of the Dzongkhags have been changed after PHCB 2005. The changes in boundary have been incorporated in this projection exercises. The affected Dzongkhags include Dagana, Trashigang, Thimphu, Punakha, Sarpang, Samdrupjongkhar and Pemagatshel. If adjustments of data are not re-aligned to the boundary changes, the comparability of population data over time might be lost.

VII. NATIONAL URBAN-RURAL POPULATION PROJECTION

The URGD method is basically developed to project Urban and Rural population when total national population has been already projected. This method uses the ratio of the urban and rural growth difference.

The proportion of urban population in 1985 was 13.1 percent and 30.9 percent in 2005 based upon which urban and rural population growth rates were estimated separately. Between 1985 and 2005, the urban population grew at an average rate of 6.1 percent and that of rural, 0.63 percent.

The URGD methods may be used under the two assumptions of constant value of 'g' at the level observed for the recent period; that is the urban-rural growth difference remains the same throughout the projection period. Or the changing value of 'g', i.e. the urban-rural growth difference will change over the projection period

Normally in developing countries, the urban growth is more rapid than that of rural areas. The urban growth difference may not remain constant. Projection with constant 'g' would come out to be too high as urban-rural growth difference cannot remain constant but narrow down over a period of time. The error might be more for those countries where 'g' is large and proportion urban is low. To overcome this problem, UN (1984) has derived a mechanism which ensures a decline in 'g' as the level of urbanization increases. The UN (1980,1984) provided the following linear relationship: $g_h = 0.044 - 0.028 U(o)$. Where g_h is the hypothetical value of the urban-rural growth difference; U(o) is initial proportion urban. Projection of urban rural projection is based upon varying value of 'g'.

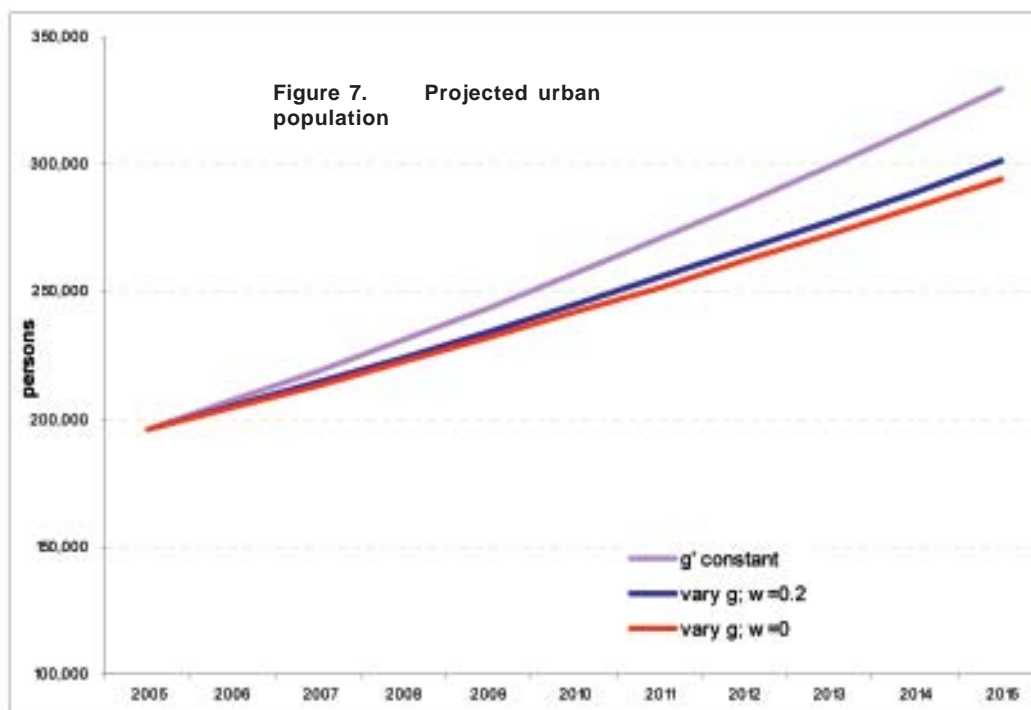

Although, projection with varying 'g' was considered, it was compared with the results from constant 'g' and different UN weights. Results may be found in the graphical representation below. The results from varying 'g' with UN weight of 0.0 are considered for the urban population projection.

The results were very close to each other, except that the projections under linear constant 'g' method exceeded the ones projected under varying 'g' and 'weight'. The results from three scenarios under which urban population projection was attempted for Bhutan, are presented below graphically. It is observed that the estimates arrived at using constant 'g' over the projection period is much higher than estimates using the UN weights. The projected figure using weights of 2 and 0 yields a much closer levels.

The population in urban and rural is the result based upon the URGD method, with UN weights =0.0.

The urban and rural disaggregation at the Dzongkhag level was projected under the assumption that the proportion of the sub-area i.e. urban with a Dzongkhag will proportionately increase at the same pace as the overall urban growth. The sex distribution within urban and rural was under the assumption that the overall sex ratio in a Dzongkhag urban area will remain constant during the projection period.

Urban population is projected to grow from 196,111 in 2005 to 294,042 persons in 2015. Urban population is estimated to grow at an annual rate of 4.2 percent while rural population will grow comparatively at a much lower rate of less than 1 percent during the projection period.

VIII. LIMITATION OF THE POPULATION PROJECTION RESULTS

Accurate baseline data on population size and age structure, as well as on fertility, mortality, and net migration rates, are critical to producing accurate population projections (Keilman 1990). So, too, are accurate data on past trends in population dynamics and vital rates, which play an important role in informing forecasts of future trends. The population projections undertaken herein are subject to, firstly the quality of data utilized. The accuracy of the projections will also depend much on the estimations made on fertility rates, mortality rates and the migration assumptions under which the projections were undertaken.

While several options exist in the choice of methodologies and techniques, their suitability and use is severely limited in Bhutan by the availability of basic data required for their application. Methodologies and techniques applied in projecting the population of Bhutan at national and Dzongkhag levels, for both urban and rural dwellers, as well as in making specific Dzongkhag population projections, are determined by the availability of these fundamental data. The utility and accuracy of the projected population depends largely on how such assumptions on fertility, mortality and migration hold through the projection period.

Bhutan conducted its first Census in 2005 and the reliable trend data that are desirable for population projection are scarce. Projections had to be based on one point of time data, as for instance the net migration rates at the Dzongkhag levels and only a few points of time fit a curve for these population parameters. Accuracy of the projections are therefore subject to the reliability of these data and the assumptions that are made about them.

It should be noted that policy changes and interventions that may directly or indirectly influence these components of population change can have significant impact on projection figures. For example, invigorating health programmes and interventions that affect mortality levels and patterns will determine the actual course of mortality, and ultimately may cause the population size to vary from projections. Similarly, health and other social programmes with direct or indirect impact on determinants of fertility will reshape the population size, as will policies and development activities that influence migration.

Accuracy of the projections is expected to be far more reliable at the national than the Dzongkhag levels. Indeed, reliability of the estimates is likely to drop significantly depending on how small a Dzongkhag division is assessed. Ratio Method projections assume that each Dzongkhag population is growing at the same rate as that of national population; however, this is precise only for short-term projections and may dwindle in reliability over the longer term. Accuracy of result at Dzongkhag level from the Ratio Method also will be affected by the thrust of development programmes in specific Dzongkhags, which can stimulate faster population growth within them.

The boundary of some Dzongkhag has changed since the last PHCB 2005. The database of PHCB 2005 was first updated to incorporate these boundary changes and the population size for each area. The results of the population projection are based upon updated data and should reflect the changes in population within each Dzongkhag. This should also allow comparability of data among the Dzongkhag areas. The accuracy of data for each Dzongkhag area will however, depends on the consistency of the geographic boundary in the future.

TABLE A-1 : PROJECTED POPULATION BY AGE GROUP AND SEX, BHUTAN, 2006 - 2007

Age group	2006			2007		
	Male	Female	Both Sex	Male	Female	Both Sex
0-4	34,382	34,015	68,397	36,687	36,232	72,919
5-9	33,969	33,253	67,222	33,134	32,519	65,653
10-14	36,857	35,517	72,374	36,334	35,127	71,461
15-19	36,740	34,421	71,161	36,836	34,788	71,624
20-24	35,584	31,278	66,862	35,753	31,858	67,611
25-29	32,425	27,514	59,939	33,113	28,208	61,321
30-34	27,286	22,587	49,873	28,235	23,485	51,720
35-39	22,866	18,797	41,663	23,560	19,342	42,902
